1. [5 marks] Determine whether the following function h on the region  $\Omega_0$  is convex, strictly convex, concave, strictly concave, or neither.

$$h(x_1, x_2) = \frac{x_1^2}{x_2}, \quad \Omega_0 = \{(x_1, x_2) \in \mathbb{R}^2 \mid x_2 > 0\}.$$

**Solution.** The gradient and the Hessian of h are given by

$$\nabla h(x_1, x_2) = \begin{pmatrix} \frac{2x_1}{x_2} \\ -\frac{x_1^2}{x_2^2} \end{pmatrix}, \text{ and } \nabla^2 h(x_1, x_2) = \begin{pmatrix} \frac{2}{x_2} & -\frac{2x_1}{x_2^2} \\ -\frac{2x_1}{x_2^2} & \frac{2x_1^2}{x_2^3} \end{pmatrix}.$$

Then,  $\operatorname{tr}(\nabla^2 h(x_1, x_2)) = \frac{2}{x_2} + \frac{2x_1^2}{x_2^3} > 0$  on  $\Omega_0$  and  $\det(\nabla^2 h(x_1, x_2)) = \frac{4x_1^2}{x_2^4} - \frac{4x_1^2}{x_2^4} = 0$ , implying that one of the eigenvalues is zero and the other is positive. Hence,  $\nabla^2 h(x_1, x_2)$  is positive semi-definite on  $\Omega_0$ , and h is a convex function on  $\Omega_0$ .

2. [15 marks] Consider the problem of optimizing the function

$$f(\mathbf{x}) = x_1^4 + 2x_2^4 + 2x_1^2x_2^2 - 2x_1^2 - 4x_2^2 + 2$$

on  $\mathbb{R}^2$ . The gradient and Hessian of f are given respectively by

$$\nabla f(\boldsymbol{x}) = 4 \begin{pmatrix} x_1(x_1^2 + x_2^2 - 1) \\ x_2(x_1^2 + 2x_2^2 - 2) \end{pmatrix}, \text{ and } \nabla^2 f(\boldsymbol{x}) = 4 \begin{pmatrix} 3x_1^2 + x_2^2 - 1 & 2x_1x_2 \\ 2x_1x_2 & x_1^2 + 6x_2^2 - 2 \end{pmatrix}.$$

i) Find the five stationary points of f on  $\mathbb{R}^2$ .

**Solution.** Solving  $\nabla f(\boldsymbol{x}) = 0$  requires that

$$x_1(x_1^2 + x_2^2 - 1) = 0, (1)$$

and

$$x_2(x_1^2 + 2x_2^2 - 2) = 0. (2)$$

It follows from Eqn. (1) that  $x_1 = 0$  or  $x_1^2 + x_2^2 - 1 = 0$ . When  $x_1 = 0$ , Eqn. (2) gives  $x_2 = 0$  or  $x_2 = \pm 1$ , so (0,0), (0,1), (0,-1) are stationary points. When  $x_1^2 + x_2^2 - 1 = 0$ , we require  $x_2 = 0$  or  $x_1^2 + 2x_2^2 - 2 = 0$  from Eqn. (2). Solving  $x_1^2 + x_2^2 - 1 = 0$  and  $x_2 = 0$  gives the stationary points (1,0) and (-1,0). Finally, solving  $x_1^2 + x_2^2 - 1 = 0$  and  $x_1^2 + 2x_2^2 - 2 = 0$  gives the stationary points (0,1) and (0,-1). In conclusion, the stationary points are

$$\boldsymbol{a} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \boldsymbol{b} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \boldsymbol{c} = \begin{pmatrix} -1 \\ 0 \end{pmatrix}, \boldsymbol{d} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \boldsymbol{e} = \begin{pmatrix} 0 \\ -1 \end{pmatrix}.$$

ii) Identify, as far as possible using Hessian information, the five stationary points of f as (strict) local minimizers, (strict) local maximizers or saddle points, etc.

**Solution.** • For  $\mathbf{a} = (0,0)^T$ , the Hessian matrix is  $\nabla^2 f(\mathbf{a}) = 4 \begin{pmatrix} -1 & 0 \\ 0 & -2 \end{pmatrix}$ . The eigenvalues of  $\nabla^2 f(\mathbf{a})$  are -4 and -8, so  $\nabla^2 f(\mathbf{a})$  is negative definite. By the second-order sufficient optimality conditions,  $\mathbf{a}$  is a strict local maximiser of f.

- For  $\mathbf{b} = (1,0)^T$ ,  $\nabla^2 f(b) = 4 \begin{pmatrix} 2 & 0 \\ 0 & -1 \end{pmatrix}$ . The eigenvalues are  $\lambda_1 = 8 > 0$  and  $\lambda_2 = -4 < 0$ , so  $\nabla^2 f(\mathbf{b})$  is indefinite, and  $\mathbf{b}$  is a saddle point of f.
- For  $\mathbf{c} = (-1,0)^T$ ,  $\nabla^2 f(\mathbf{c}) = 4 \begin{pmatrix} 2 & 0 \\ 0 & -1 \end{pmatrix}$ , which is indefinite, and  $\mathbf{c}$  is a saddle point of f.
- For  $\mathbf{d} = (0,1)^T$ ,  $\nabla^2 f(\mathbf{d}) = 4 \begin{pmatrix} 0 & 0 \\ 0 & 4 \end{pmatrix}$ , which is positive semi-definite as the eigenvalues are 0 and 16. It is not enough to conclude that  $\mathbf{d}$  is a local minimiser, but we can conclude that  $\mathbf{d}$  is not a local maximiser by the second-order necessary conditions for a local maximizer.
- For  $e = (0, -1)^T$ ,  $\nabla^2 f(e) = 4 \begin{pmatrix} 0 & 0 \\ 0 & 4 \end{pmatrix}$ , which is positive semi-definite, so e cannot be a local maximiser of f by the second-order necessary conditions for a local maximizer.
- iii) Does the function f have a global maximizer on  $\mathbb{R}^2$ ? Give reasons for your answer.

**Solution.** The function f does not have a global maximiser because

$$f(x_1, 0) = x_1^4 - 2x_1^2 + 2 = (x_1^2 - 1)^2 + 1 \to +\infty$$

as  $x_1 \to +\infty$ , and the function is not bounded above on  $\mathbb{R}^2$ .

3. [4 marks] Let A be a real  $(n \times n)$  square matrix. Let  $a_{ii}$  and  $a_{jj}$  be the  $i^{th}$  and  $j^{th}$  diagonal elements of A respectively, where  $i, j \in \{1, 2, ..., n\}$  and  $i \neq j$ . Using the definition of an indefinite matrix, show that if  $a_{ii}a_{jj} < 0$ , then A is indefinite.

Proof. We take the standard basis vectors  $\mathbf{e}_i \in \mathbb{R}^n$ , which has entry 1 on the *i*-th component and zero otherwise, and  $\mathbf{e}_j \in \mathbb{R}^n$ , which has entry 1 on the *j*-th component and zero otherwise,  $\mathbf{e}_i \neq \mathbf{e}_j$ . Then,  $\mathbf{e}_i^{\top} A \mathbf{e}_i = a_{ii}$  and  $\mathbf{e}_j^{\top} A \mathbf{e}_j = a_{jj}$ . We consider two scenarios when  $a_{ii}a_{jj} < 0$ , i.e.,  $a_{ii} < 0$ ,  $a_{jj} > 0$  or  $a_{ii} > 0$ ,  $a_{jj} < 0$ . For the former scenario,  $\mathbf{e}_i^{\top} A \mathbf{e}_i < 0$  and  $\mathbf{e}_j^{\top} A \mathbf{e}_j > 0$ . By the definition, A is an indefinite matrix. For the latter scenario,  $\mathbf{e}_i^{\top} A \mathbf{e}_i > 0$  and  $\mathbf{e}_j^{\top} A \mathbf{e}_j < 0$ , again implying that A is indefinite.

4. [6 marks] Let C be an  $m \times n$  matrix,  $\mathbf{d} \in \mathbb{R}^m$ ,  $\mathbf{a} \in \mathbb{R}^n$  and  $r \in \mathbb{R}$ . Show that

$$\Omega = \{ \boldsymbol{x} \in \mathbb{R}^n : \| \mathbf{C}\boldsymbol{x} - \boldsymbol{d} \| \le \mathbf{a}^{\mathsf{T}}\boldsymbol{x} + r \}$$

is a convex set for any norm  $\|\cdot\|$  on  $\mathbb{R}^m$ . State any properties of a norm that you use.

*Proof.* Let  $\boldsymbol{x}, \boldsymbol{y} \in \Omega$  and  $\theta \in (0, 1)$  be arbitrary. Then,  $\|C\boldsymbol{x} - \boldsymbol{d}\| \leq \boldsymbol{a}^{\top}\boldsymbol{x} + r$  and  $\|C\boldsymbol{y} - \boldsymbol{d}\| \leq \boldsymbol{a}^{\top}\boldsymbol{y} + r$ . Define  $\boldsymbol{z} = \theta \boldsymbol{x} + (1 - \theta)\boldsymbol{y}$ . We need to show that  $\boldsymbol{z} \in \Omega$ .

$$||Cz - d|| = ||C(\theta x + (1 - \theta)y) - d||$$

$$= ||\theta Cx + (1 - \theta)Cy - \theta d - (1 - \theta)d||$$

$$= ||\theta (Cx - d) + (1 - \theta)(Cy - d)||$$

$$\leq ||\theta (Cx - d)|| + ||(1 - \theta)(Cy - d)||$$
 (triangle inequality)
$$= |\theta|||Cx - d|| + |1 - \theta|||Cy - d||$$
 (positive homogenity)
$$= \theta||Cx - d|| + (1 - \theta)||Cy - d||$$
 ( $\theta > 0$  and  $\theta > 0$ )
$$\leq \theta(a^{T}x + r) + (1 - \theta)(a^{T}y + r)$$

$$= a^{T}(\theta x + (1 - \theta)y) + r$$
 ( $a^{T}x$  and  $a^{T}y$  are linear in  $x$  and  $y$  respectively)
$$= a^{T}z + r.$$

Hence,  $z \in \Omega$ , and by the definition of convexity,  $\Omega$  is a convex set.
